Q-Step Edinburgh Jupyter Notebook

Jupyter Notebooks a Quick-Step Towards Literate Computing and Reproducible Research

The work is very exploratory.

Positive comments are always appreciated, but brickbats improve work.

or @profbigvern

Next Actions: Demonstrate at Q-Step Edinburgh Meeting 26th January 2017

Author: Professor Vernon Gayle

Project: Reproducible Research with Administrative Social Science Data

Sub-project: Jupyter Notebooks / Social Science Data Analysis with Python

Latest Update: 25th January 2017 University of Edinburgh

Previous Updates: 24th January (back on Scotrail - delay at Linlithgow) 23rd January 2017 (on

Scotrail) 22nd January 2017 University of Edinburgh

My General Motivation

Can we use Jupyter Notebooks to support reproducible social science research?

Are there insights we can gain from computer science & e-Research?

Are there insights from Open Science?

Overview

The Jupyter Notebook is an open source web application that facilitates the creation and sharing of documents that contain live code and supporting commentary in the form of explanatory text.

It is platform that can be used throughout the research process to organise and articulate elements of the social science workflow.

The Jupyter Notebook is open source and currently supports interactive data science and scientific computing across over 40 programming languages.

Obvious uses include data enabling and management, statistical analyses, simulations, and machine learning, but it is sufficiently flexible to be used more widely.

Jupyter Notebooks & Big Science

The detection of gravitational waves is heralded as a major scientific discovery.

Here is a video of Fernado Perez demonstrating a Jupyter Notebook that includes data and analyses of the first observed gravitational waves which are from the LIGO collaborations.

click on picture to run video

For more information on how this important work was rendered openly accessible by the LIGO collaboration see https://losc.ligo.org/s/events/GW150914/GW150914_tutorial.html .

Counting Galaxies in the Hubble Deep Field

This example uses the image-processing library scikit-image to identify galaxies in an image of the sky provided by the Hubble Space Telescope using a blob feature detection algorithm (an approach known as the determinant of Hessian).

After running the cell, we can explore the parameters of the detection algorithm to find galaxies of different sizes and prominences:

The max_sigma parameter determines the maximum size of the objects tha t will be identified

The threshold parameter can be reduced to detect less prominent object S

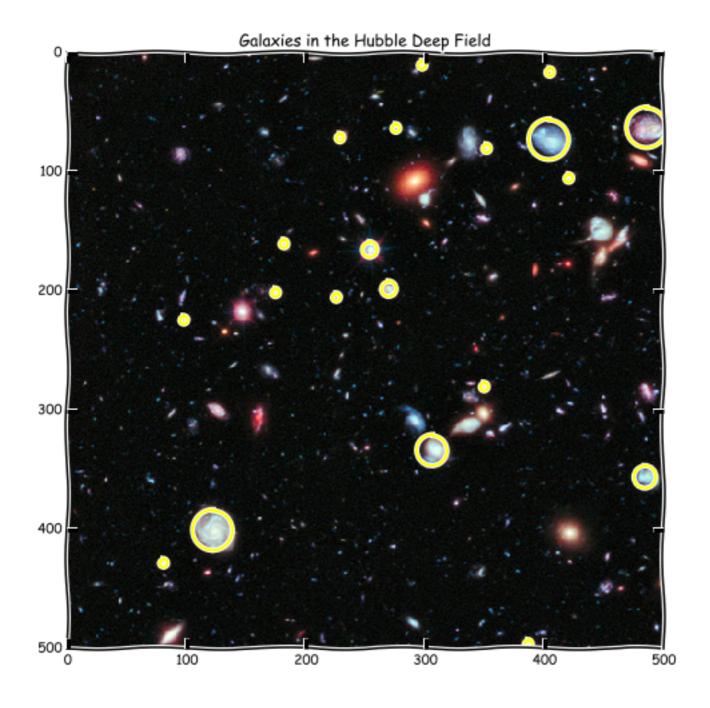

This example was provided in a live example hosted by the journal Nature

http://www.nature.com/news/ipython-interactive-demo-7.21492?article=1.16261

```
In [47]: # Import matplotlib (plotting), skimage (image processing) and interact (user
         interfaces)
         # This enables their use in the Notebook.
         %matplotlib inline
         from matplotlib import pyplot as plt
         from skimage import data
         from skimage.feature import blob doh
         from skimage.color import rgb2gray
         from IPython.html.widgets import interact, fixed
         # Extract the first 500px square of the Hubble Deep Field.
         image = data.hubble_deep_field()[0:500, 0:500]
         image_gray = rgb2gray(image)
         def plot_blobs(max_sigma=30, threshold=0.1, gray=False):
             Plot the image and the blobs that have been found.
             blobs = blob_doh(image_gray, max_sigma=max_sigma, threshold=threshold)
             fig, ax = plt.subplots(figsize=(8,8))
             ax.set_title('Galaxies in the Hubble Deep Field')
             if gray:
                 ax.imshow(image_gray, interpolation='nearest', cmap='gray_r')
                 circle color = 'red'
             else:
                 ax.imshow(image, interpolation='nearest')
                 circle color = 'yellow'
             for blob in blobs:
                 y, x, r = blob
```

```
c = plt.Circle((x, y), r, color=circle_color, linewidth=2, fill=False
        ax.add_patch(c)
# Use interact to explore the galaxy detection algorithm.
interact(plot_blobs, max_sigma=(10, 40, 2), threshold=(0.005, 0.02, 0.001));
# The max_sigma parameter determines the maximum size of the objects that wil
1 be identified
# The threshold parameter can be reduced to detect less prominent objects
```

Out[47]: <function __main__.plot_blobs>

Literate Computing

Fernando Perez says

Literate Computing is the weaving of a narrative directly into a live computation, interleaving text with code and results to construct a complete piece that relies equally on the textual explanations and the computational components, for the goals of communicating results in scientific computing and data analysis.

http://blog.fperez.org/

Why is it call Jupyter?

The computer languages Julia Python and R almost spell **JuPyteR**

The original authors Fernando Perez and Brian Granger are physicists.

Galileo's notebooks are an inportant early milestone (or deliverable) in open science.

Galileo's notes directly integrated his data (drawings of Jupiter and its moons), key metadata (timing of each observation, weather, telescope properties), and text (descriptions of methods, analysis, and conclusions) see https://www.authorea.com/users/3/articles/6316/ show article.

Two obvious examples are Sidereus Nuncius and la vacchetta (which literally means the small cow

or calf, because of the leather of its binding).

Translations of these notebooks can be viewed here

http://www.dioi.org/galileo/galileo.htm

http://homepages.wmich.edu/~mcgrew/Siderius.pdf

Three Galilean moons of Jupiter are visible on the logo.

Some people may have come accross IPython Notebooks which are from an earlier stage in the evolutionary process.

Jupyter Notebooks and Social Surveys and Administrative **Social Science Data Analysis**

Jupyter Notebooks have a number of attractive features

- 1. Easy documentation alongside research code
- 2. 'Language agnostic' 40+ languages
- 3. Rich visual outputs
- 4. Big data tools e.g. python
- 5. Teaching and training
- 6. Collaborative work
- 7. Portability (publication) easy to share

These features are demonstrated in this Jupyter Notebook.

Structure of a Jupyter Notebook

A Jupyter Notebook is made up of cells.

A cell can contain either

- i. live research code (e.g. Stata syntax) that can be executed
- ii. text comments that form the documentation of the research workflow
- iii. cells that contain the results of data analyses

In addition to running your code the Notebook frontend stores code and output, together with markdown notes, in an editable document called a notebook. When you save it, this is sent from your browser to the notebook server, which saves it on disk as a JSON file with a .ipynb extension.

Documentation in the Jupyter Notebook

Writing comments and documenting research code in a Jupyter Notebook is relatively easy.

Notebooks use *Markdown*, which is explained below.

Comments can also be included within research code. For example a comment within Stata code can be written by starting with the familiar asterisk or star symbol.

Markdown

Markdown is an easy way to write documents.

It is written in what computer geeks like to call 'plaintext'. It is the sort of text that we are used to writing and seeing.

Plaintext is just the regular alphabet plus a few other familiar symbols (for example the asterisk *).

Unlike cumbersome word processing applications, text written in Markdown can be easily shared between computers.

It's quickly becoming the writing standard in some academic areas and in science.

Websites like GitHub and reddit use Markdown to style their comments.

Here is a summary of *Markdown* codes https://en.wikipedia.org/wiki/Markdown#Example .

If you have half an hour you can learn Markdown here http://www.markdowntutorial.com/ (you might need to use Internet Explorer).

Examples

Example 1 'Sitting in the Swivel Chair' (undertaking data analyses in different languages)

Example 2 'Rich Visual Output'

Example 3 'Widgets'

Example 4 'Using Magic Cells'

Example 5 'A Gnarly Example in Stata with a Complex Model'

Example 1 'Sitting in the Swivel Chair'

The Notebook can work with over 40 programming languages.

This includes data analysis software such as Stata and R and languages such as Python that are popular in some areas of data science.

Moving between languages with ease has been likened to sitting in an office chair and swivelling between three different computers.

The example below demonstrates some social science data analysis (estimating a logistic regression model) within the Jupyter Notebook.

To illustrate that the Jupyter Notebook is 'language agnostic', the analysis is undertaken using Stata, R and Python.

Jupyter Notebooks use different 'kernels' to work in different languages.

Stata Analysis

Stata is a proprietary software package and you MUST have access to the software to run it within a Jupyter Notebook.

Here is a link to the Stata Corporation http://www.stata.com/.

This is an example of running Stata from within the Jupyter Notebook.

The live research code in each cell is Stata syntax.

Comments are written in cells using markdown.

WARNING

We would usually use a Stata Kernel to run Stata.

In this current example we will use MAGIC - which will be explained later in this notebook.

This is because some users with Windows 10 machines have experienced problems installing the Stata Kernel.

MAGIC cells are explained later in the notebook.

import ipystata In [48]:

The cell above imports ipystata to run Stata

see http://dev-ii-seminar.readthedocs.io/en/latest/notebooks/Stata in jupyter.html

The cell below imports the Stata data file from my website vernongayle.com.

```
In [49]: | %%stata -o wemp_df
         use "http://www.vernongayle.com/uploads/2/2/3/0/22304498/wemp.dta", clear
         codebook, compact
```

R Analysis

WARNING

You must have R installed on your machine.

You must have installed the R kernel (See https://anaconda.org/r/r-irkernel).

You must have installed the R libraries foreign and survey

for example run the code install.packages("foreign", "survey")

(see https://cran.r-project.org/web/packages/survey/index.html; https://cran.rproject.org/web/packages/foreign/index.html).

Reminder *Switch Kernel to R < Menu kernel - change kernel>*

Getting the libraries for R

```
In [1]: library(foreign)
        library(survey)
        Loading required package: grid
        Attaching package: 'survey'
        The following object is masked from 'package:graphics':
            dotchart
```

If you have an error message here it is possibly because you have not switched to the R Kernel

Getting the Stata data file (.dta) into an object called "mydata" then summarizing the dataset

```
mydata <- read.dta("http://www.vernongayle.com/uploads/2/2/3/0/22304498/wemp.</pre>
In [2]:
        dta")
        summary(mydata)
Out[2]:
              case
                                femp
                                                  mune
                                                                     time
                                                                    : 0.0

The R results are the same as the Stata results - thankfully

Python Analysis

WARNING *Switch Kernel to Python < Menu kernel - change kernel>*

Switch Kernel to Python 3 < Menu kernel - change kernel>

```
In [10]: import pandas as pd
```

Construct the data frame "df" reading in the data from an Excel (xlsx) file. It could also be read in from a csv file.

Out[11]:

	case	femp	mune	time	und1	und5	age
(1	1	0	10	1	1	23
•	1	0	0	11	0	1	24
2	1	0	0	12	0	1	25
3	1	0	0	13	0	1	26
4	6	1	0	0	0	0	42

Python is more general purpose and not primarily orientated towards social science data analysis. Therefore some things are a little more fiddly. For example we must set a constant for all case (int=1).

Examining the data in the data frame "df".

In [6]: df.head()

Out[6]:

	case	femp	mune	time	und1	und5	age	Int
0	1	1	0	10	1	1	23	1
1	1	0	0	11	0	1	24	1
2	1	0	0	12	0	1	25	1
3	1	0	0	13	0	1	26	1
4	6	1	0	0	0	0	42	1

Import the package "statsmodels".

```
In [7]: import statsmodels.api as sm
```

Estimate a logistic regression model the independent variables are "mune" "und5" and "int" the outcome variable is "femp".

```
In [8]: independentVar = ['mune', 'und5', 'Int']
        logReg = sm.Logit(df['femp'] , df[independentVar])
        answer = logReg.fit()
```

Optimization terminated successfully. Current function value: 0.556127 Iterations 5

The results are in the object "answer".

In [9]: answer.summary()

Out[9]:

Logit Regression Results

Dep. Variable:	femp	No. Observations:	1580
Model:	Logit	Df Residuals:	1577
Method:	MLE	Df Model:	2
Date:	Tue, 24 Jan 2017	Pseudo R-squ.:	0.1446
Time:	09:56:39	Log-Likelihood:	-878.68
converged:	True	LL-Null:	-1027.2
		LLR p-value:	3.056e-65

	coef	std err	z	P> z	[95.0% Conf. Int.]
mune	-1.7033	0.236	-7.222	0.000	-2.166 -1.241

Int	1.3068	0.074	17.561	0.000	1.161 1.453

The result are the same in Python, R and Stata - Phew!

Summary

This example was designed to demonstrate that Jupyter Notebooks are language agnostic.

The language agnostic aspects of Jupyter Notebooks mean that they could be an appropriate unified environment in which to undertake research analyses using alternative software packages and languages.

This feature is especially attractive in some collaborative endeavours. For example Stata is the primary data analysis software package at the ADRC-Scotland. From time to time there may be a requirement to used other data analysis tools.

Example 2 'Rich Visual Output'

There are several visual features of Jupyter Notebooks that make them attractive as environments in which to undertake analyses of social science data and which might also enrich teaching, training and kwonledge exchange and research capacity building activities.

Here is a smart wee example that shows the flexibility of graphing within the Jupyter Notebook.

This wee example runs in Python. You MUST have the Python kernel running.

Make sure you have the wemp data in the the "df" data frame.

In [13]: df.head()

Out[13]:

		case	femp	mune	time	und1	und5	age	age2
)	1	1	0	10	1	1	23	529
,	1	1	0	0	11	0	1	24	576
2	2	1	0	0	12	0	1	25	625
,	3	1	0	0	13	0	1	26	676
4	4	6	1	0	0	0	0	42	1764

If you can't see the wemp data you need to go back up and reload it in the Python part of the Example 1.

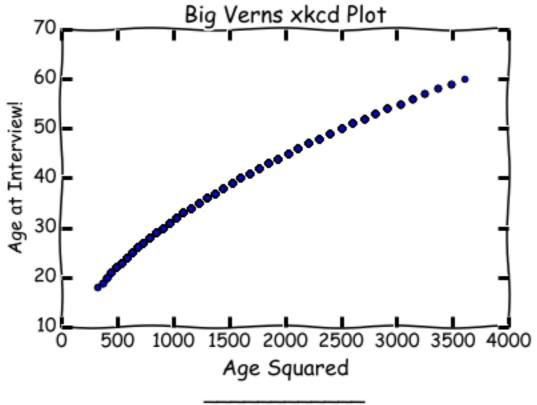

We will now construct a new variable called age2 which is the woman's age squared.

This is an example of a graph in the style of a xkcd comic.

```
In [15]: %pylab inline
         plt.xkcd() # Yes...
         fig1 = plt.figure(1)
         ax1 = fig1.add_subplot(111)
         ax1.scatter(df['age2'], df['age'],)
         plt.title('Big Verns xkcd Plot')
         plt.ylabel('Age at Interview!')
         plt.xlabel("Age Squared\n"
                     "Another inventive use of the wemp dataset", size=16)
```

Populating the interactive namespace from numpy and matplotlib

Out[15]: <matplotlib.text.Text at 0xee3f252470>

Another inventive use of the wemp dataset

see http://nbviewer.jupyter.org/url/jakevdp.github.com/downloads/notebooks/XKCD_plots.ipynb

Inserting a picture into the notebook (within a markdown cell).

Donald Knuth

Inserting a video into the notebook (within a markdown cell).

In [1]: from IPython.display import YouTubeVideo YouTubeVideo('p47tetYy7co')

Out[1]:

To render cell contents as LaTeX.

```
In [17]: %%latex
      \begin{align}
      a = \frac{1}{2} \&\& b = \frac{1}{2} \&\& c = \frac{1}{4} \
      \end{align}
      In [18]: %%latex
      e^{i\pi} + 1 = 0
```

$$e^{i\pi} + 1 = 0$$

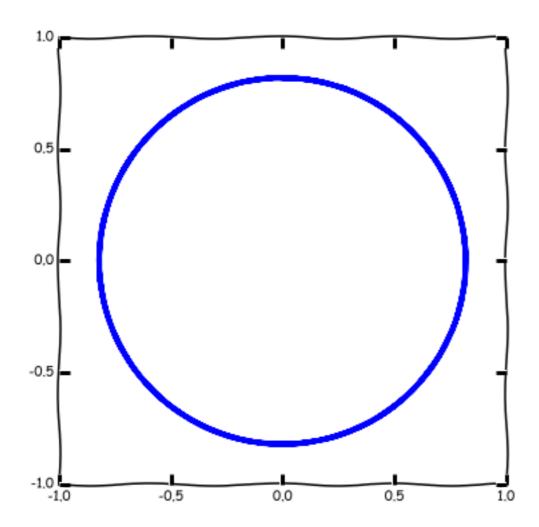

Code can produce rich output such as images, videos, LaTeX, and JavaScript.

Example 3 'Widgets'

Widgets are clever devices that can be included in notebooks to help users visualize and control changes in the data. Widgets may be useful in teaching and training because users can easily see how changing inputs to something impacts on the results.

An Interesting Wee Widget

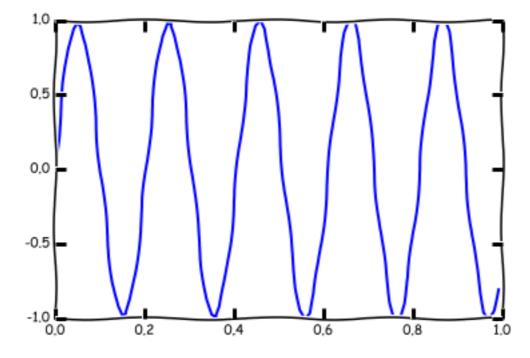

```
In [19]: %matplotlib inline
         import matplotlib.pyplot as plt
         from numpy import pi, exp, real, imag, linspace
         from ipywidgets import interact
         def f(t, a=1, b=6, c=-14, d=0):
              return \exp(a^*1j^*t) - \exp(b^*1j^*t)/2 + 1j^*\exp(c^*1j^*t)/3 + \exp(d^*1j^*t)/4
         def plot_swirly(a=1, b=6, c=-14, d=0):
              t = linspace(0, 2*pi, 1000)
              ft = f(t,a,b,c,d)
              plt.plot(real(ft), imag(ft))
              # These two lines make the aspect ratio square
              fig = plt.gcf()
              fig.set_size_inches(6, 6, forward='True')
         interact(plot_swirly, a=(-20, 20), b=(-20, 20), c=(-20, 20), d=(-20, 20));
```

The Sine Wave Example

```
In [20]: from ipywidgets import widgets
         import numpy as np
         import matplotlib.pyplot as plt
         from IPython.display import display
         from numpy import arange, sin, pi
         %matplotlib inline
```

```
In [21]: from IPython.html.widgets import *
         t = arange(0.0, 1.0, 0.01)
         def pltsin(f):
             plt.plot(t,sin(2*pi*t*f))
             plt.show()
         interact(pltsin, f=(1,10,0.1))
```

Out[21]: <function __main__.pltsin>

Example 4 'Using Magic Cells'

Any cell that starts with a % symbol or two symbols %% is a 'magic' cell (honestly that is what they are called).

Here are a list of some of the standard 'magics'.

In [22]: %lsmagic

Out[22]: Available line magics:

%alias %alias_magic %autocall %automagic %autosave %bookmark %cd %clea r %cls %colors %config %connect_info %copy %ddir %debug %dhist %dirs %doctest_mode %echo %ed %edit %env %gui %hist %history %install_defau It config %install ext %install profiles %killbgscripts %ldir %less %lo ad %load ext %loadpy %logoff %logon %logstart %logstate %logstop %lsmagic %macro %magic %matplotlib %mkdir %more %notebook %page %past ebin %pdb %pdef %pdoc %pfile %pinfo %pinfo2 %popd %pprint %precision %profile %prun %psearch %psource %pushd %pwd %pycat %pylab %qtconsole %quickref %recall %rehashx %reload_ext %ren %rep %rerun %reset %reset selective %rmdir %run %save %sc %set env %store %sx %system %tb %t ime %timeit %unalias %unload_ext %who %who_ls %whos %xdel %xmode

Available cell magics:

%%HTML %%SVG %%bash %%capture %%cmd %%debug %%file %%html %%java script %%latex %%perl %%prun %%pypy %%python %%python2 %%python3 %%ru by %%script %%sh %%svg %%sx %%system %%time whimeit %%writefile

Automagic is ON, % prefix IS NOT needed for line magics.

In Example 1 we used a non-standard magic to run Stata which was written by Ties de Kok

```
In [23]: %time print ("How long does this cell take to run?")
```

How long does this cell take to run? Wall time: 1 ms

Example 5 'A Really Gnarly Example in Stata with a Complex Model'

Multilevel mixed-effects generalized linear model in Stata (meglm)

Multilevel modeling of survey data is a little different from standard modeling in that weighted sampling can take place at multiple levels in the model, resulting in multiple sampling weights.

Most survey datasets, regardless of the design, contain one overall inclusion weight for each observation in the data. This weight reflects the inverse of the probability of ultimate selection (i.e. it factors in all levels of clustered sampling, corrections for noninclusion and oversampling, poststratification).

Rabe-Hesketh, S. and Skrondal, A., 2006. Multilevel modelling of complex survey data. Journal of

the Royal Statistical Society: Series A (Statistics in Society), 169(4), pp.805-827.

Rabe-Hesketh and Skrondal (2006) analyzed data from the 2000 Programme for International Student Assessment (PISA) study on reading proficiency among 15-year-old American students, as performed by the Organisation for Economic Co-operation and Development (OECD).

In [1]: import ipystata In [2]: **%%stata** use http://www.stata-press.com/data/r14/pisa2000, clear (Programme for International Student Assessment (PISA) 2000 data) In [3]: %%stata codebook, compact

Variable	0bs	Unique	Mean	Min	Max	Label
female	2069	2	.5432576	0	1	1 if female
isei	2069	58	47.0435	16	90	International socio
w_fstuwt	2069	224	843.3753	130.3095	3858.783	Student-level weight
wnrschbw	2069	147	167.8744	15.41	3352.32	School-level weight
high_school	2069	2	.3412276	Θ	1	1 if highest level b.
college	2069	2	.578057	Θ	1	1 if highest level b.
one_for	2069	2	.0560657	0	1	1 if one parent fore.
both_for	2069	2	.117448	0	1	1 if both parents ar.
test_lang	2069	2	.9134848	0	1	1 if English (the te.
pass_read	2069	2	.3881102	Θ	1	1 if passed reading .

For student i in school j, where the variable id_school identifies the schools, the variable w_fstuwt is a student-level overall inclusion weight (wij, not wiji) adjusted for non-inclusion and non-participation of students, and the variable wnrschbw is the school-level weight wj adjusted for oversampling of schools with more students from minority groups.

Rabe-Hesketh and Skrondal (2006) fit a two-level logistic model for passing a reading proficiency threshold. We will do the same using meglm, but first we must adjusted the weight variables that were used. We need adjustment scales for the first-level weights so that they sum to the effective sample size of their corresponding second-level cluster.

```
In [29]:
         %%stata
         sort id school
         generate sqw = w fstuwt * w fstuwt
         by id_school: egen sumw = sum(w_fstuwt)
         by id_school: egen sumsqw = sum(sqw)
         generate pst1s1 = w fstuwt*sumw/sumsqw
```

The new variable pst1s1 holds the adjusted first-level weights.

Rabe-Hesketh and Skrondal (2006) also included the school mean socioeconomic index as a covariate in their analysis. We reproduce this new variable mn isei.

```
In [30]:
         %%stata
         by id_school: egen mn_isei = mean(isei)
```

Estimation a multi-level logistic regression model with complex survey data.

```

Here we have specified a multi-level logit model (or a random effects logit model).

The survey data are complex.

Pupils are nested in schools and we are adjusting the model for both school-level and pupil-level weights.

- 1] We specified the level-one weights using standard Stata weight syntax [pw=pst1s1].
- 2] We specified the level-two weights via the pweight(wnrschbw) option as part of the random effects specification for the id_school level using the syntax || id_school:, pweight(wnrschbw). The weight wnrschbw needs to be constant within schools.
- 3] The standard errors in the presence of sampling weights are robust.
- 4] Robust standard errors are clustered at the top level of the model, and this will always be true unless you specify vce(cluster clustvar), where clustvar identifies an even higher level of grouping.

This is illustration is drawn from Example 5 of the meglm section of Stata Manual (pp.81-82).

A Little Light Relief

My Jupyter Limerick

A researcher with time to fritter

Decided he didn't need Jupyter

His results he would show

Without a traceable workflow

Could a researcher be any stupider?

Remarks and Conclusion

Jupyter Notebooks and Social Surveys and Administrative Social Science Data Analysis

Jupyter Notebooks have a number of attractive features

- 1. Easy documentation alongside research code
- 2. 'Language agnostic' 40+ languages
- 3. Rich visual outputs
- 4. Big data tools e.g. python
- 5. Teaching and training
- 6. Collaborative work
- 7. Portability (publication) easy to share

These features are demonstrated in this Jupyter Notebook.

Finally converting this Jupyter Notebook into Portable **Formats**

see http://nbconvert.readthedocs.io/en/latest/

- 1. At the cmd prompt conda install nbconvert
- 2. Change directory (for example my directory is *C:\Users\Vernon*
- 3. Type jupyter nbconvert --to html mynotebook.ipynb

The work is very exploratory.

Positive comments are always appreciated, but brickbats improve
